## PREFACE

The 2017 - 2038 Population Projections Report is one of a number of reports that have been derived from the 2017 Population and Housing Census. This report contains projected counts of the future population. The projections are presented at national, rural/urban residence and regions.

The main purpose of producing population projections is to provide estimates of the future population for use in planning, policy formulation and decision making in various sectors of the economy. This assists the planning process in presenting a future outlook of the population.

Heart-felt appreciation goes to the United Nations Population Fund (UNFPA) for making it possible to produce the projections report through her continued financial and technical support. The Central Statistical Office is grateful to the author, Mr Fredrick Okwayo, Regional Technical Advisor, UNFPA East and Southern Africa Regional Office, for the final production of the report.

It is also worth noting and appreciating that without the cooperation and well-coordinated participation of the Demography and Vital Statistics Staff, Data Processing Staff, GIS Staff and Ministry of Health Statistics Unit, this report would not have been a success.

## EXECUTIVE SUMMARY

This report presents population projections for the Kingdom of Eswatini, for urban and rural areas of the country, and for the four regions, based on the 2017 Eswatini Population and Housing Census. The projection variants are based on different assumptions about the future trends in fertility, mortality, international and internal migration. Three assumptions were made regarding fertility changes while one plausible assumption each was made for mortality and migration.

For the national, rural and urban areas and the regions, annual projected population numbers are given from 2017 to 2038. Projected population numbers refer to 1 July, the midpoint of the Government's fiscal year and calendar year. Numbers of births, deaths, and internal and international migrants are given for years beginning 1 July and ending 30 June. The medium variant projects a total population of 1,247,532 and 1,432,235 persons in 2027 and 2038, respectively. The corresponding low and high variant totals are 1,243,064 and 1,268,869 persons in 2027 and 1,407,889 and 1,500,078 persons in 2038, respectively (Table 3.1).

The population growth rate will be steady over the projection period, around 1.2 per cent per annum. This is attributed to declining birth rates and corresponding less net international migration rates. Decreasing crude birth rates from 28.9 in 2017 to 21.6 in 2038 and crude death rates, from 8.8 in 2017 to 7.9 in 2038 are the main reason for the decline. Crude birth rate declines steadily through the projection period as a result of increased level of education of women while in the case of death rates, declines result from expanded access to antiretroviral (ARVs) for the management of HIV infection and improved health care system, which increases life expectancy at birth. Net international outmigration reduces population growth, but not by much. The estimated crude rate of international net migration rates declines from negative (-7.71 per thousand in 2017 to -1.04) per thousand in 2038.

The age dependency ratio in the population declines over the projection period, from 68.9 in 2017 to 56.4 in 2038 over the projection period. The child dependency ratio declines from 60.5 to 46.2, between 2017 and 2038. Ageing dependency ratio rises from 7.6 to 10.2 during the projection period, underscoring the need for the country to start preparing for an ageing population.

In the medium variant projection, the proportion of the urban population rises from 23.7 percent in 2017 to 26.5 percent in 2038.

Medium variant projections for the four regions of the country show Manzini Region growing more rapidly than any other region, its share of the national population will increase from 32.6 in 2017 to 34.0 per cent in 2038 (Table 5.5). Another rapidly growing region is Hhohho. The other regions, Shiselweni and Lubombo would experience declining proportion of their population as a share to the overall population mainly due to rural to urban migration.

The projected demographic trends may be beneficial to economic growth and development of the country if well harnessed. When the ratio between the dependent and the working age population decreases, new economic and social opportunities arise: families tend to increase their saving capacity, the pressure on several government services (for example, education) declines, the number of adults that pay taxes increases, and families can invest more in each child. This period is called the demographic window of opportunity. This window can lead to the reaping of the demographic bonus or demographic dividend. It is important to point out, however, that the demographic window by

itself cannot guarantee development and economic growth. To reap the demographic dividend, the country must formulate and implement policies that, among others, create enough opportunities in the labour market, support investments in health to ensure a healthy labour force and facilitate further demographic transition through enhancing voluntary family planning services and access to effective modern contraception. All the regions are projected to enter into the demographic bonus window. The economic and social implications of the future population growth and changes in the age composition presented in this report should be seriously considered in the national development plans and other policy instruments.

**Table I: Summary of Demographic Indicators, Eswatini 2017-2038**

| Indicator                       | Year      |           |           |           |           |           |

# CHAPTER 1: INTRODUCTION

This report presents the population projection estimates for the Kingdom of Eswatini based on the 2017 Population and Housing Census. It provides projected population size by age and sex for the national, urban and rural areas of the country, and each of the four regions. The projected population refers to 1st July of the indicated year, the midpoint of the calendar year. Population projections from previous population censuses were done with the same reference points, so this will enable comparisons with earlier estimates.

The population projections for national, urban and rural and the four regions are provided for 2018 to 2038, a 20-year period. The end year was chosen based on the validity of the assumptions made on components of population change; the longer the period, the less plausible are the assumptions. In the context of a high HIV and AIDS epidemic as in the Kingdom of Eswatini, a short time horizon is desirable to minimize uncertainties. Hence, the projection period was set at 20 years, from 2018 to 2038.

The span of any population projection deserves important consideration. It should be informed by, among other things, the uses to which the projection results are to be put. The longer the time horizon of a projection, the larger would be the uncertainty that would be associated with the results. A short projection horizon of 10 to 20 years is generally recommended.

## Population Projections

Population projections are calculations of future population size and composition generated using the data from previous and latest censuses as well as indicators derived from household-based surveys. The calculations estimate future birth rate, death rate and migration patterns of the population. The projection calculations are based on assumptions considered to best reflect recent patterns of fertility, mortality and migration. These assumptions are formulated based on the analysis of past data trends and plausible future trends. However, it is not possible to know how these patterns may change in future. To reflect this uncertainty, different variant projections are produced implying different sets of alternative future scenarios which will generate the population projections.

## Potential Uses of Population Projections

The primary needs of the Eswatini people, which development programmes aim to satisfy cannot be gauged rationally without regard to the expected population size, composition, distribution and their characteristics at different administrative units and points in time. Some of the ways in which population projections estimates can be used include: -

**Distribution of Resources** – the planning processes always use the population projections numbers. The planners at national, region and other subnational administrative levels in a country need to have accurate information on the likely future changes in the size, composition and distribution of the population in their respective administrative areas. The regions in the country have greater demand for projected population figures at subnational level so that services such as education, health care, housing, among others are budgeted for accurately.

**Research** – researchers always use projections in order to try to answer questions that relate to the future. However, population change can equally be regarded as being, to some extent, a dependent rather than independent variable in the planning process. As such, population projections would be used to estimate the likely demographic impact of planning decisions and policy changes, as well as planning and policy implications of demographic change. Population projections can also be used to guide sampling for representative surveys.

**Advocacy** – Population numbers serve an advocacy purpose, especially where there is an impact of a particular phenomenon on population or vice versa. Examples include ongoing discussions on the demographic dividend, consequences of high adolescent birth rates on future potentials of women and girls, effects of high birth rates on social sector spending, population and environment interactions, population policies, among others.

**Monitoring and Evaluation** – population projections are an important input for programmes not only during target setting, but also for monitoring and evaluation, especially at impact level. Projection figures are also useful in assessing whether a country is on track in achieving national and international development targets, like the Sustainable Development Goals (SDGs), Africa Union Agenda 2063 – Africa we Want, International Conference on Population and Development (ICPD), Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW), the National Development plan and sectorial plans, among others. Most of programme indicators in monitoring progress need census population figures as denominators. In this sense, projected population provide denominator (base) to many such development indicators.

## CHAPTER 2. METHODOLOGY AND ASSUMPTIONS

There are several methods of projecting populations (mathematical, economic and cohort-component methods), with varying levels of sophistication and rigor. Identifying which projection model is optimal for a specific type of projection depends on several factors. The critical point to remember when choosing a projection method is that no single model or technique is better than others for all purposes. Rather, each model or projection method has its strengths and weaknesses and must be evaluated according to its face validity, timeliness, cost, data requirements, ease of application and interpretation, and other characteristics.

The 2017-2038 Eswatini population projections used the cohort-component method. Using the initial population distributed by five-year age groups and sex, the method projects the population by updating the population of each age- and sex-specific group according to assumptions about three components of population change: fertility, mortality, and migration. The projected size and age structure of the population at specific point in the future depends entirely on the size and age structure at the beginning of the period and the age-specific fertility, mortality, and migration rates over the projection period. Hence preparation of population projections depends critically upon establishing a reliable base population, such as that provided by a census, the likely future trends of fertility, mortality and migration during the projection period, based on knowledge of past trends in each of these components, socio-economic changes and population policies expected to take place during the projection period.

The quality of the census data was evaluated to inform preparation of a reliable baseline population for the projection exercise. The past trends in fertility, mortality, and migration were carefully analysed and current levels and patterns established from the 2017 census. The projection of the probable future course of the components of population change was then conducted in the context of existing demographic history, existing policies, including the Strategic Roadmap 2019-2023, National Development Plan 2019/2021-22, Plan Vision 2022, and the National Population Policy, all of which identify socio-economic changes that are anticipated to take place during the projection period.

### Choice of Population Projection Software

This projection was made using the Rural-Urban Projection (RUP) Program developed by the US Census Bureau. The RUP program uses a cohort-component method to project the population by single years of age and sex. RUP has an editor that allows interactive entry of empirical age-specific schedule of mortality. It also has a number of features that allow a considerable amount of flexibility in specifying projected trends in fertility, mortality and migration compared with other frequently used population projection programs. RUP uses the empirical and projected age-specific schedules of mortality provided, and appropriate separation factors specified, to generate a series of life Tables. Using interpolated values of central death rates from the life Tables, RUP estimates the number of deaths and subtracts them from each cohort. It also takes into account internal and international migration. It estimates births for each year of the projection using fertility rates and the female population in the reproductive ages. The annual number of births constitutes new population cohorts that are followed through in the course of the projection period. Its output also includes a variety of demographic indicators that allow a detailed examination of the results and their use in decision making process.

For a population like Eswatini where the HIV and AIDS epidemic has had a significant impact on mortality and population age sex structure in the past, and affected both life expectancy at birth and the age-sex pattern of mortality, the use of the age pattern of mortality in the model life tables is not appropriate. This is because the age pattern of mortality may have departed significantly from the patterns described in the model life tables. In this case, life tables were estimated based on data on recent deaths in households collected from the census.

## 2.1 Urban/Rural and Region Projections

At the second level of the projections were the urban and rural as well as the regional projections. Due to data limitations regarding mostly net migration at urban/rural as well as regional levels, the cohort component method was not appropriate for projecting the populations at these levels. The ratio method of projections was therefore applied.

### Urban and Rural Projections

In applying the ratio method for the urban/rural projections, first, the proportion of the urban population to the national population and similarly for the rural to national population was computed for each of the last four censuses (1986, 1997, 2007 and 2017). Secondly, these observed ratios were extrapolated to the end of the projection period under the assumption that the observed trends in the ratios will continue to the end of the projections period. Thirdly, the projected ratios for the urban and rural were applied separately to the projected cohort component projection of the national population for each of the projection period to obtain the projected urban/rural populations for each of the projection period. The procedure in the case of the urban population may be expressed algebraically as follows:

$$U(t) = N(t) * r(t)$$

Where: -

$U(i,t)$  is the projected urban population in a specific time period  $t$ ,

$N(t)$  is the projected national population at time  $t$ ,

$r(t)$  is a projected ratio of the urban population to the projected national population at time  $t$ .

## 2.2 Region Projections

A similar approach used in the urban/rural projections was applied in projecting the regional populations. For each of the four regions, the proportions of the regional population to the national population in each of the 1986, 1997, 2007 and 2017 censuses were computed. These observed ratios were then extrapolated for each region to the end of the projection period under the assumption that the observed trends in the ratios will continue to the end of the projections period. For each of the four regions, the projected regional population for each projection year was obtained by applying the projected ratio for the region for that year to the projected cohort component projection of the national population for the same year.

A similar logic was used in disaggregating the urban/rural projections by age and sex as well as the regional projections by age and sex. Although the ratio method does not explicitly use fertility, mortality and net migration data, they are incorporated indirectly into the projections. Projections figures for rural/urban as well as regions were generated based on medium variant assumptions.

### 2.3. Adjusting the base population

The single year population age distribution from the 2017 Census showed some digit preference in ages ending in seven and eight. There was also some heaping in ages ending in one and three, but this was less pronounced than the former. In comparison with some other African populations, the single year age distribution from the Eswatini 2017 census was considered reasonably good.

The five-year age population pyramid showed indentation in the 0-4 age group. This is a common feature in African censuses. The indentation cannot be attributed to fertility decline or increased mortality of children under the age of five years in the five years preceding the census. It was therefore necessary to smooth the five-year age distribution. If smoothing was not carried out, all other things equal, the projected population of the 0-4 age group in each proceeding five years would be under-projected, and this would have adverse effect for planning in some sectors such as education and health. Smoothing of the adjusted population was done using the Arriaga method.

The adjusted base population was then moved from the date of enumeration to the midyear using the growth rate based on estimated fertility, mortality and migration. The actual date of enumeration was 29 April 2017 and the national population was moved to mid-year (1<sup>st</sup> July 2017). The MOVEPOP spreadsheet in PAS program developed by the US Census Bureau was used for the advancement of the population to mid-year. The urban/rural and regional populations were adjusted so that their sum equals that of the national population (by age group and sex). Table 2.1 shows the enumerated and mid-year adjusted populations by sex and region. The mid-year population which is both adjusted for under-reporting and moved to July 1<sup>st</sup> 2017 was thereafter used to make projections.

**Table 2.1 Enumerated and adjusted population by region and sex, Eswatini 2017 Census**

| Region        | Enumerated Population<br>(2017 Census) |         |           | Base Population<br>(adjusted and moved to 1 July 2017) |         |           |
|---------------|--|---------|-----------|--|---------|-----------|
|               | Male                                   | Female  | Total     | Male   | Female  | Total     |
| Eswatini      | 531 111                                | 562 127 | 1 093 238 | 538 957  | 567 494 | 1 106 451 |

## 2.4 Assessment of Quality of 2017 Census Data

Data collection in censuses all over the world is often affected by problems of administration and logistics. These often give rise to coverage and content errors, which vary both in nature and magnitude from one country to another and may differ even within regions in the same country. Coverage errors result from omission of certain pockets of the population, while content errors pertain to misreporting or misclassification of events. These errors lead to biases and distortion in the estimates based on such data.

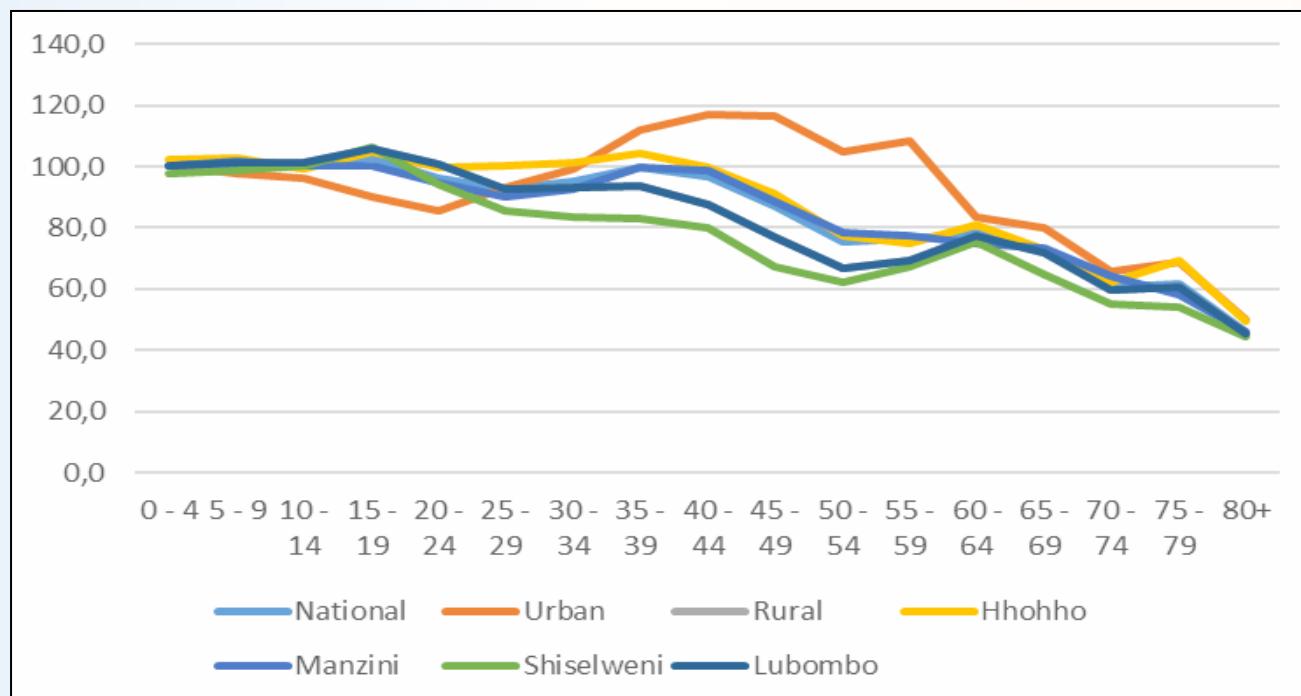

Although all modern censuses collect information on age and sex of the population, the data often contain errors because some people do not know their true age while others do not report their age accurately. The distribution of a population by age and sex is one of the most basic yet important information needed for future planning. Given the importance of the age structure with respect to social and economic characteristics, it is imperative that the information on the population by age and sex be as accurate as possible. For this reason, it is critical to evaluate the reported age and sex composition of the population before undertaking population projections.

### 2.4.1 Coverage errors

Coverage errors may occur in various ways: omitting a dwelling unit that should have been included; including a housing unit more than once; or including a housing unit in an administrative unit that should not have been included. In spite of the fact that massive efforts are made in providing good training and up-to-date cartographic maps to the field staff, as well as introducing checks and controls throughout the fieldwork, such errors still occur. Consequently, any census data should be always checked for any inconsistencies as a result of such errors. Various techniques have been developed for checking for such inconsistencies, key among which is the use of sex ratios.

### 2.4.2 Sex ratios

Sex ratio is an analytical tool calculated by dividing the male population in a given age group by the female population in the same age group, multiplied by 100. The larger the abrupt departure of this ratio from values close to 100, the larger the possibility of errors in the data. All populations have more males than females at births, and so the sex ratio at the early ages is expected to be slightly over 100. However, since mortality is usually higher for males than females, the sex ratio is reduced continuously up to the oldest ages. Sex Ratios below 100 denote under-coverage while those above 100 would imply double counting. Figure 2.1 depicts sex ratios for Eswatini, urban/rural and regions.

**Figure 2.1 Sex Ratios by Age, Rural/Urban and Regions, Eswatini 2017 Census**

The figure shows that on average, the sex ratio at national and all other domains (regions and urban/rural place of residence) are as expected. The sex ratio for urban indicates higher than 100 sex ratio for ages between 30 to 60 years. This is because more men than females live in urban areas within these ages due to employment opportunities.

#### 2.4.3 Content errors

One of the basic but vital information provided by a census is the age profile of the population. Population data in developing countries are often subject to age misreporting. This is often due to low literacy levels of respondents in some rural areas, low educational qualification of census enumerators and limited robust field quality control checks. Irregularities in the age distribution may be a result of a respondent's incorrect age declaration or the interviewer who estimates the age of a respondent who does not know his or her age. It is, therefore, important to evaluate the accuracy of the age distribution and correct for deficiencies wherever necessary. The principal approaches for evaluating age misreporting are digit preference and age ratios.

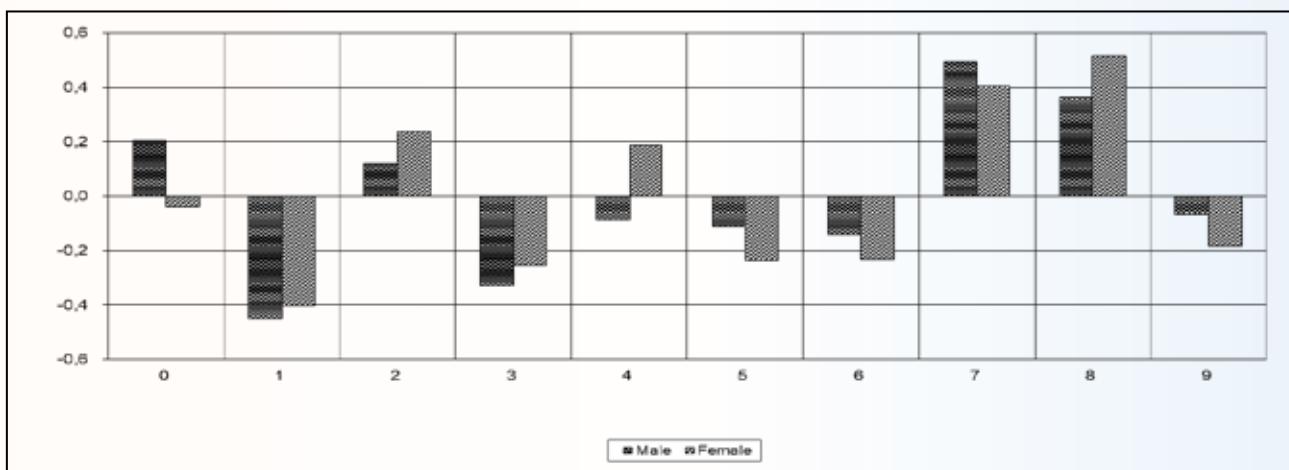

#### 2.4.4 Digit preference

Digit preference or age heaping is a common error that occurs in age reporting. It is the result of deliberate misstatement or knowledge of age on the part of the respondent. Irregularities in reporting of age can be detected by using various indices which detect digit preference at the terminal digits. By means of such indices, several methods have been developed to detect irregularities in reporting age.

To quantify the magnitude of digit preference, the Myer's Index was used. This index assesses digit preference in all the 10 terminal digits (0-9). Every one of the ten terminal digits takes 10 percent out of 100. In an ideal situation where there is no digit preference, the terminal digit will score a total of 10 percent.

A deviation from 10 percent shows either digit preference (a positive deviation value), suggesting that people prefer reporting their age ending with those digits or digit avoidance (a negative deviation value). Digit preference, using Myers Index, for the 2017 census data is illustrated in Figure 2.2.

**Figure 2.2 Digit Preference by Sex, Myers Index, Eswatini, 2017**

Terminal digits (7 and 8) were highly preferred with females and males preferring eight and seven, respectively. The preference or avoidance of digits was balanced in the census. Most people avoided reporting age ending with digit one followed by digit three. This shows better quality of age reporting as there is no clustering of ages ending with zero and five as is often reported in most data collection exercises.

Whipple's index is a method to measure the tendency for individuals to inaccurately report their actual age or date of birth. Respondents to a census sometimes report their age or date of birth as a round number (typically ending in 0 and 5), for example, so that they appear younger or to have been born on a date ending in zero or five. The process of reporting a rounded age is known as age-heaping.

Table 2.4 shows the Whipple's Index for 1976 to 2017 censuses. It is evident that the quality of age reporting has improved over time. The data quality of the 2007 and the current census are reflected as highly accurate data. This therefore indicates that there has been less age heaping for ages ending with digits '0' and '5'. The 2017 census is showing a marginal improvement over the 2007 census in age reporting. It can further be noted that there are no significant differences in age reporting between males and females.

**Table 2.4 Whipple's Index by Sex, 1976 – 2017, Eswatini Censuses**

| Sex    | Census Year |       |       |       |       |
|--------|-------------|-------|-------|-------|-------|
|        | 1976        | 1986  | 1997  | 2007  | 2017  |
| Total  | 131.4       | 125.9 | 120.6 | 99.1  | 99.7  |
| Male   | 158.0       | 125.4 | 121.5 | 100.5 | 100.5 |
| Female | 137.7       | 133.0 | 119.7 | 97.8  | 98.9  |

## 2.5 Assumptions

### Mortality and Fertility Assumptions

Table 2.5 shows the mortality and fertility assumptions made for the national projections for all the three variants. The mortality assumptions are expressed in terms of the female and male life expectancy at birth. The initial values for both age specific fertility rate and life expectancy at birth were based on the *Eswatini 2017 Population and Housing Census Volume 4: Fertility, Nuptiality, Mortality and Civil Registration*. The life expectancy at birth trends were calculated using a model of mortality decline developed by the United Nations Population Division from estimates of levels and trends for a large number of countries. The model provides a choice between low, medium, and high increases in life expectancy at birth. Female life expectancy at birth in Eswatini was 63.5 years in 2017, a great increase from 43.1 years according to the 2007 Census results. The tremendous increase in life expectancy at birth is mostly attributed to wide availability and utilization of antiretroviral in HIV and AIDS management and other advances in healthcare systems in the country. The male-female difference in life expectancy is large, approximately 4.6 years. Considering the current life expectancy at birth level, the slow increase model of the UN model was therefore used for both males and females. The fertility assumptions take account of past trends detailed in the same publication, and of fertility decline in other African countries with similar contexts in Southern Africa region. The pattern of age specific fertility rate for this projection was reworked based on the UN model as the pattern generated from the census data is not plausible in Africa. In the 2017 Census analysis, women aged 15 to 29 contributed to only 25 percent of current births, whereas according to the UN Model Tables of the Age Distribution of Fertility for Sub-Saharan African and studies done by censuses and demographic and health surveys in Africa, women aged 15 to 29 contribute 63 percent of current births. There were also review of trends generated from household based surveys as well as plausible impact of the ongoing educational, health and social interventions in the country.

**Table 2.5 Mortality and fertility assumptions for the low, medium and high variant National projections, 2017 - 2038**

| Year | Expectation of life at birth |        | Total Fertility Rate |        |      |
|------|------------------------------|--------|----------------------|--------|------|
|      | Male                         | Female | Low                  | Medium | High |
| 2017 | 58.9                         | 63.5   | 3.23                 | 3.23   | 3.23 |
| 2020 | 60.9                         | 65.5   | 2.90                 | 3.00   | 3.10 |
| 2025 | 62.9                         | 67.5   | 2.70                 | 2.70   | 3.10 |
| 2030 | 64.9                         | 69.0   | 2.50                 | 2.60   | 3.00 |
| 2035 | 66.8                         | 70.5   | 2.38                 | 2.51   | 2.90 |
| 2038 | 66.8                         | 70.5   | 2.10                 | 2.50   | 2.90 |

### International Migration Assumptions

The Eswatini 2017 Census contained questions on place of birth, place of residence, current residential status of household members, duration of residence outside Eswatini for former household members staying outside the country, citizenship and reasons for migration. Estimates of immigrants and emigrants, and therefore net international migrants were derived by age and sex from these data and are contained in the Migration section of *Eswatini 2017 Population and Housing Census Volume 3: Population Structure and Composition, Religion, Internal and International Migration and urbanization Based*

on observed decline in the annual net number of international migrants due to the decline in the South Africa mining industry, and the industrial reforms anticipated by the national development plan to attract foreign investors and facilitate job creation, it is assumed that nationals who are currently living outside the country may be prompted to come back home. This assumption was used to forecast migration patterns.

In collaboration with the Census Technical team, additional efforts were made to review existing patterns of emigration including in countries where people are likely to be living and the plausible trends based on the UNSD Population Projections for the country. Two assumptions on international migration were made. First, for projection year ending June 2018, following the age-sex pattern of emigration, the total net international outmigration rate was assumed to be negative 7.4 per one thousand population. This number is based on the average annual number of departures during the five years prior to the census indicated by the data on conventional household members abroad.

**Table 2.6 Estimate of net international migration, Eswatini 2017 Census**

| <b>Age group</b> | <b>Net International Migrants</b> |               |                   |
|------------------|-----------------------------------|---------------|-------------------|
|                  | <b>Male</b>                       | <b>Female</b> | <b>Both sexes</b> |
| 0-4              | 508                               | 504           | 1013              |
| 5-9              | 363                               | 307           | 671               |
| 10-14            | 172                               | 109           | 281               |
| 15-19            | -209                              | -407          | -617              |
| 20-24            | -1,154                            | -1,352        | -2,506            |
| 25-29            | -1,657                            | -1,437        | -3,094            |
| 30-34            | -1,431                            | -934          | -2,365            |
| 35-39            | -804                              | -595          | -1,400            |
| 40-44            | -342                              | -229          | -571              |
| 45-49            | -306                              | -175          | -482              |
| 50-54            | -146                              | 12            | -134              |
| 55-59            | -27                               | 32            | 5                 |
| 60-64            | 87                                | 54            | 141               |
| 65-69            | 66                                | 76            | 142               |
| 70-74            | 87                                | 77            | 164               |
| 75-79            | 31                                | 45            | 96                |
| 80+              | 51                                | 98            | 129               |
| Total            | -4,712                            | -3,815        | -8,527            |

The second assumption was that net international outmigration rate will continue, but that numbers of out-migrants will decline. Specifically, it was assumed that the number of net international out-migration rate will be negative 2.5 per thousand population in 2025-2030 and become positive 1.5 in the 2030-2035, and to positive 1.4 in the last projection period of 2035-2040. The assumptions on migration is shown in Table 2.4. These net international migration rates are used for all projection variants. Only one assumption relating to projections of migration size and pattern was used to avoid a profusion of projection scenarios.

## Projection Variants

Conventionally, three sets of projections are often produced and can be classified as low, medium and high variants. Since population projections are made on the basis of certain assumptions relating to birth rate, death rate and migration, the interplay of these three parameters will yield the variant of interest. Usually, the high variant assumes that the birth rate is high, death rate is low, immigration rate is high and emigration rate is low.

The medium variant assumes that there is medium increase in birth rate and death rate and medium increase in immigration rate and emigration rate. Such a projection shows a medium increase in the growth rate of population due to other factors such as improvement in contraceptive prevalence rate, educational achievements, job opportunities and healthcare services. For the low projection variant, the assumption is that birth rate is low and death rate is high and both immigration and emigration rates are also high, leading to a low projected population.

The medium variant is the one which is most likely to provide accurate estimates in most circumstances, while the low and high variants will provide an indication of the uncertainty surrounding the medium series constituting the highest and the lowest boundary of population estimates. The detailed assumptions by variant are provided in Section 2.5 and Table 2.7.

**Table 2.7 Summary of Assumptions for Low, Medium and High Variants**

| Variant               | Assumptions  |
|-----------------------|--|
| <b>Low Variant</b>    | Total fertility rate declines from 3.23 in 2017 to 2.5 in 2025 and to replacement level 2.1 in 2038. Life expectancy at birth improves from 58.9 years for males and 63.5 years for females in 2017 to 66.8 years for males and 70.35 years for females in 2038. Annual negative net migration of 4,712 males and 3,815 females for the beginning of the projection year and thereafter declines to the end of the period. |
| <b>Medium Variant</b> | Total fertility rate declines from 3.23 in 2017 to 2.7 in 2025 and to 2.5 in 2038. Life expectancy at birth improves from 58.9 years for males and 63.5 years for females in 2017 to 66.8 years for males and 70.35 years for females in 2038. Annual negative net migration of 4,712 males and 3,815 females for the beginning of the projection year and thereafter declines to the end of the period.                   |
| <b>High Variant</b>   | Total fertility rate declines from 3.23 in 2017 to 3.1 in 2025 and to 2.9 in 2038. Life expectancy at birth improves from 58.9 years for males and 63.5 years for females in 2017 to 66.8 years for males and 70.35 years for females in 2038. Annual negative net migration of 4,712 males and 3,815 females for the beginning of the projection year and thereafter declines to the end of the period.                   |

## CHAPTER 3: RESULTS SUMMARY

### 3.1 National Population Projections

The projections presented in this report refers to the mid-year population. Table 3.1 shows the projected population, by sex, from 2017 to 2038 for all the three variants. The total population for Eswatini is projected to increase from 1,106,451 to 1,432,235 persons between 2017 and 2038 assuming the medium variant scenario. The population would be 1,500,078 and 1,407,889 persons, if we take the high and low variant scenarios, respectively. In 20 years' time, the population in Eswatini is expected to increase by about 326,000 people assuming medium variant.

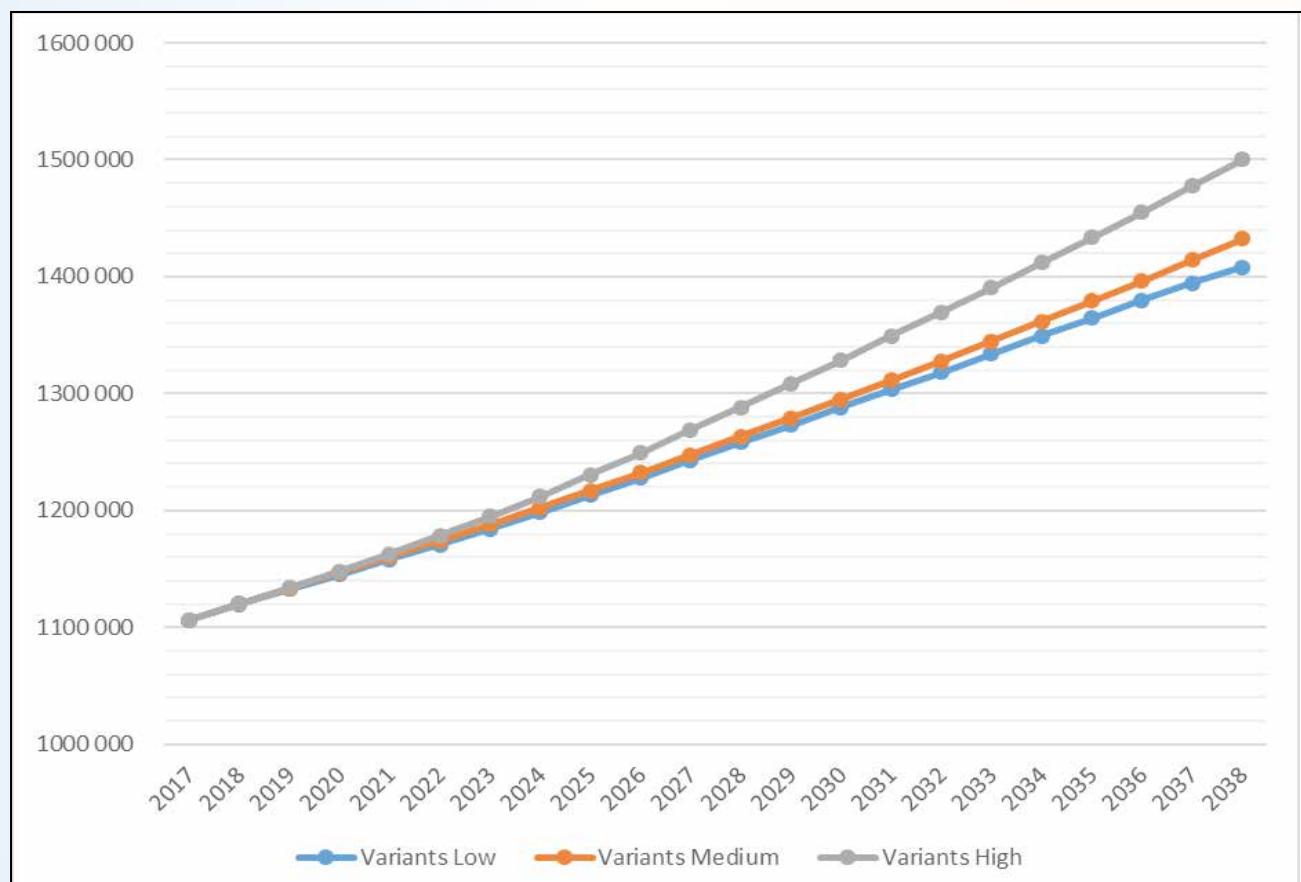

**Table 3.1: Summary of National Population Projections by Sex, Low, Medium and High Variants**

| Year | Low Variant |         |            | Medium Variant |         |            | High Variant |         |            |
|------|-------------|---------|------------|----------------|---------|------------|--------------|---------|------------|
|      | Male        | Female  | Both Sexes | Male           | Female  | Both Sexes | Male         | Female  | Both Sexes |
| 2017 | 538 957     | 567 494 | 1 106 451  | 538 957        | 567 494 | 1 106 451  | 538 957      | 567 494 | 1 106 451  |
| 2018 | 545 366     | 574 556 | 1 119 922  | 545 452        | 574 640 | 1 120 092  | 545 529      | 574 715 | 1 120 244  |
| 2019 | 551 564     | 581 284 | 1 132 848  | 551 905        | 581 617 | 1 133 522  | 552 214      | 581 917 | 1 134 131  |
| 2020 | 557 640     | 587 764 | 1 145 404  | 558 399        | 588 504 | 1 146 903  | 559 097      | 589 181 | 1 148 278  |
| 2021 | 563 792     | 594 191 | 1 157 983  | 564 997        | 595 365 | 1 160 362  | 566 312      | 596 641 | 1 162 953  |
| 2022 | 570 205     | 600 749 | 1 170 954  | 571 756        | 602 258 | 1 174 014  | 573 985      | 604 422 | 1 178 407  |
| 2023 | 576 912     | 607 495 | 1 184 407  | 578 711        | 609 245 | 1 187 956  | 582 156      | 612 589 | 1 194 745  |
| 2024 | 583 949     | 614 488 | 1 198 437  | 585 899        | 616 386 | 1 202 285  | 590 868      | 621 210 | 1 212 078  |
| 2025 | 591 331     | 621 747 | 1 213 078  | 593 339        | 623 702 | 1 217 041  | 600 145      | 630 310 | 1 230 455  |
| 2026 | 598 904     | 629 149 | 1 228 053  | 600 982        | 631 172 | 1 232 154  | 609 790      | 639 725 | 1 249 515  |
| 2027 | 606 503     | 636 561 | 1 243 064  | 608 767        | 638 765 | 1 247 532  | 619 592      | 649 277 | 1 268 869  |
| 2028 | 614 128     | 643 971 | 1 258 099  | 616 695        | 646 469 | 1 263 164  | 629 556      | 658 958 | 1 288 514  |
| 2029 | 621 777     | 651 365 | 1 273 142  | 624 767        | 654 272 | 1 279 039  | 639 684      | 668 758 | 1 308 442  |
| 2030 | 629 441     | 658 735 | 1 288 176  | 632 974        | 662 169 | 1 295 143  | 649 969      | 678 671 | 1 328 640  |
| 2031 | 637 152     | 666 113 | 1 303 265  | 641 314        | 670 158 | 1 311 472  | 660 401      | 688 689 | 1 349 090  |
| 2032 | 644 936     | 673 527 | 1 318 463  | 649 782        | 678 235 | 1 328 017  | 670 962      | 698 795 | 1 369 757  |
| 2033 | 652 804     | 680 988 | 1 333 792  | 658 386        | 686 409 | 1 344 795  | 681 672      | 709 010 | 1 390 682  |
| 2034 | 660 764     | 688 505 | 1 349 269  | 667 130        | 694 685 | 1 361 815  | 692 552      | 719 355 | 1 411 907  |
| 2035 | 668 785     | 696 050 | 1 364 835  | 675 993        | 703 044 | 1 379 037  | 703 579      | 729 809 | 1 433 388  |
| 2036 | 676 632     | 703 394 | 1 380 026  | 684 995        | 711 505 | 1 396 500  | 714 792      | 740 410 | 1 455 202  |
| 2037 | 684 067     | 710 308 | 1 394 375  | 694 140        | 720 074 | 1 414 214  | 726 224      | 751 191 | 1 477 415  |
| 2038 | 691 093     | 716 796 | 1 407 889  | 703 457        | 728 778 | 1 432 235  | 737 901      | 762 177 | 1 500 078  |

The age composition of the population will not experience considerable changes during the projection period. However, there are some important variations that, although not large, suggest a trend that may have important consequences. Considering indicators of the age composition of the population, the first relevant trend is the slight decline in the percentage of children and the population age 0-14 years. The percentage of children age 0-4 years will decline from 12.2 percent of the total population

in 2017 to 11.2 percent in 2038. The percentage of the population age 0-14 years will decline from 37.4 percent in 2017 to 32.3 percent in 2038. The second important trend is the increase in the percentage of the working-age population (15-64 years). It is expected to increase from 59.5 percent in 2017 to 61.5 percent in 2038. This percentage change may not be substantial but, in absolute terms, the working-age population will increase substantially. The third relevant trend is the stability of the old age population. The population aged 65 years and over will increase from 4.5 percent to 6.2 percent in 2038. The sex ratio will remain the same during the projection period: it will increase slightly from 95.0 to 96.8. The reason seems to be the fact that survival rates have increased a little more rapidly among males than females and, therefore, the number of males increased in the population.

**Figure 3.1 Projected Population size by variants**

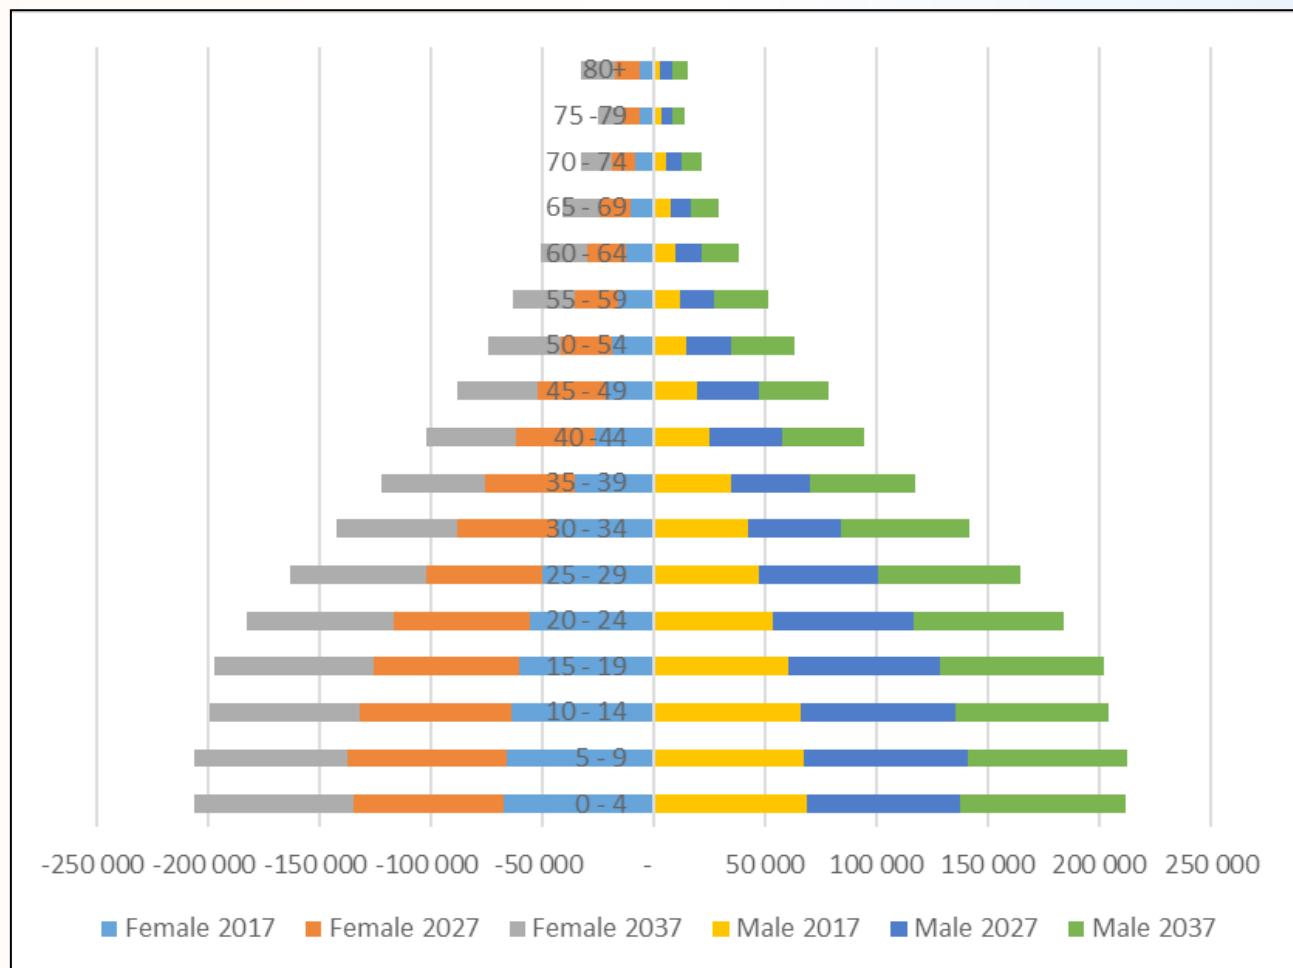

### 3.2 Projected Projections Five-year Age Groups - Medium Projection Variant

Figure 3.2 shows the superimposed population pyramids (absolute) corresponding to 2017, 2027 and 2037 of the projection period. An important feature is the shape of the first bar, the one that corresponds to the population age 0-4. In the pyramid corresponding to the last projection year (2037) this bar is the same size or shorter than the corresponding population group (5-9 years). This suggests a decline in the number of births. This is the result of the assumed fertility decline during the projection period. In the decades beyond the 2030s, it is likely that the pyramid will slightly change its profile, with a smaller number of children aged 0-4 years relative to those aged 5-9.

One can see the effect of declining fertility in the population pyramids comparing the base population pyramid with that of 2037 – as fertility declines, the population pyramid takes a more onion shape.

**Figure 3.2: Projected Five-year Age Groups - Medium Variant Base Population, 2017, 2027 and 2037**

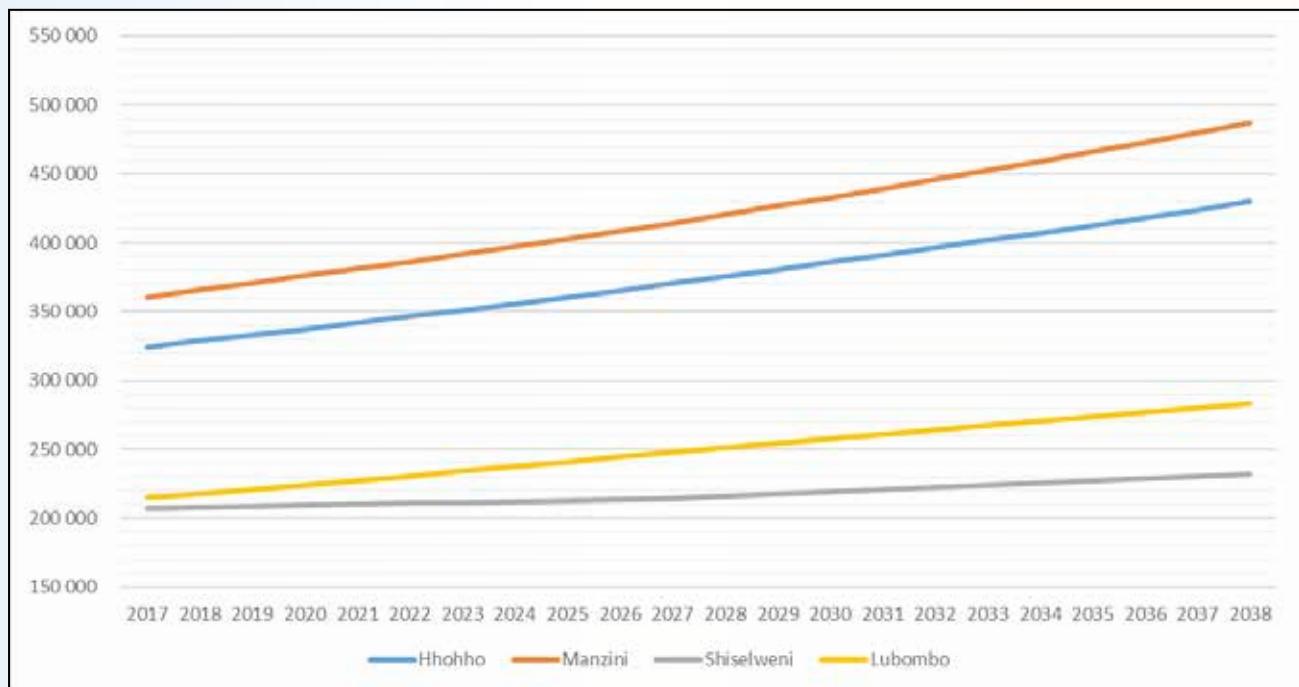

### 3.3 Projected Urban Rural Population - Medium Projection Variant

The number of persons living in rural areas is more than those living in urban areas currently and this trend is expected to continue though at a slow pace. The projection shows that the urban population will increase from 23.8 to 26.4 percent of the national population between 2017 and 2038 for the medium variant projection. This is detailed in Table I and Table 5.4.

### 3.4 Projected Regional Population - Medium Variant

As seen in Figure 3.3, while the numbers of persons living in Manzini and Hhohho regions (predominately urban) are projected to increase, the numbers of persons living in the other two regions are also projected to increase but more gradually. It is projected that people will continue to migrate from Lubombo and Shiselweni regions to Manzini and Hhohho in search of employment opportunities and better life, thereby making the growth rates minimal in those two regions. It is recommended that detailed studies are conducted to identify pull and push factors in all these regions so that relevant policies on socio-economic development and social amenities are formulated and implemented.

**Figure 3.3: Projected regional population - Medium variant**

## CHAPTER 4: CONCLUSIONS

A population census is the main source of data for planning and decision making in most sectors of the economy at both national and sub-national levels in many countries. Due to huge cost and logistical considerations, it is not possible to undertake censuses every year. Population projections are therefore a cost-effective means of providing valuable data during the intercensal period. In making assumptions to accurately predict the future course of fertility, mortality and net-migration – the components of population change – three projection scenarios are often produced with the medium variant being interpreted as the most probable course of the growth and age sex structure of the population. In the course of producing the above projections, certain limitations of the data from which the inputs of the assumptions were derived were highlighted. Despite these limitations, the population projections provide useful data that should be used by policy decision makers, programme managers, researchers and other data users to improve the welfare of the population.

In any population, after a process of fertility decline, such as the Kingdom of Eswatini has undergone and is likely to continue to experience, the large cohorts born before the decline start climbing in the population pyramid and enter into working-age. As a result, one of the challenges that is faced by countries that are undergoing this demographic transition is to implement employment policies directed to these expanding cohorts. They could be extremely beneficial for economic growth and development if there are enough opportunities in the labour market. It is considered that when the ratio between the dependent and the working population decreases, new economic and social opportunities arise. Families tend to increase their saving capacity, the pressure on several government services (for example, education) declines, the adult population that pays taxes increases, and families can invest more in each child. This period is called the demographic window of opportunity and it is considered highly favourable to socio-economic development, social investment and human development. This window provides what is called a demographic bonus or demographic dividend in reference to the opportunities provided by the demographic dynamics to increase socio-economic development and the levels of population wellbeing.

It is important to point out, however, that the demographic window by itself cannot guarantee development and economic growth. The increasing percentage of the population in working-age does not translate directly and inevitably to development. On the contrary, if the economic and social environment are unfavourable, the economy cannot absorb the working age population, and the large population of young adults may become a problem to the country. The economic and social implications of the future population growth and changes in the age composition as well as other demographic changes such as aging and a rise in the urban population presented in this report need to be seriously analysed, discussed and utilised for the benefit of the people in the county.

## GLOSSARY OF TERMS AND DEFINITIONS

**Age misreporting:** Instance where a person states his/her age wrongly by giving a value which is less or higher than actual age, either intentionally or unintentionally.

**Age ratio:** The proportion of population in a given age group to its adjacent age groups, that is the successive and the predeceasing age groups.

**Age-sex accuracy index:** An index that combines both the sex ratio and the age ratio for both male and females to develop a joint score

**Age-specific fertility rate (ASFR):** the age-specific fertility rate for a given age group and time period is the number of births to women in the age group during the time period divided by the person-years lived by women in the age group during the period. Person-years lived may be approximated by the mid-period population multiplied by the length of the period.

**Base population:** It is the starting population on which future population projections are speculated to increase from.

**Content errors:** These are errors in the characteristics of the persons counted, resulting from incorrect reporting or recording or from failure to report.

**Coverage errors:** These are non-sampling errors that result from omitting a unit that should have been included, including a unit more than once, or including a unit that should not have been included

**Cohort:** is a group of persons, followed over time, who experience a particular event during a particular time period, most commonly a birth cohort, a group of persons born during a given period, or an age cohort, the subgroup of a birth cohort who survive to a particular time.

**Components:** are quantities that add up to a given quantity. Female and male populations are components of total population. Length of unmarried life is the sum of years lived before marriage and years lived after marriage. Components most often refer to numbers of persons or to time intervals. Components may be negative, as in the “demographic equation”.

**Components of population change:** are the numbers of entries to and/or exits from a population during a time period that add up to the population change during the period. Entries may be disaggregated by births and in-migrants, and exits by deaths and out-migrants. Migrants may be disaggregated by internal migrants and international migrants.

**Dependency ratio:** shows the proportion of dependents per 100 working age population. Three different measures can be calculated: **total dependency ratio** (the sum of those aged under 15 plus those aged 65 and over per 100 aged 15-64); **child dependency ratio** (those aged under 15 per 100 aged 15-64); and **old-age dependency ratio** (those aged 65 and over per 100 aged 15-64).

**Expectation of life:** It is an estimate of the average number of additional years a person could expect to live if the age specific death rates for a given year prevailed for the rest of his/her life. This can be derived for either male or female and in most populations is slightly higher for females than for males. It is commonly referred to as life expectancy at birth, denoted by  $e(0)$ . Life expectancy can be derived at any other age based on the current death rates.

**HIV Prevalence:** Prevalence is the percent of people who have a given disease in a population; hence HIV prevalence is the percentage of people who have been infected by HIV in a population at a particular point in time.

**International migration:** is the migration of persons between countries.

**Life expectancy at birth:** is the average number of years a new-born child is expected to live if the mortality conditions of the year corresponding to the life table remain constant. Expectation of life at birth is denoted by  $e0$ .

**Migration/Migrant:** a migration is defined generally as a move from one “migration-defining area” to another that was made during a given migration interval and that involved a change of residence. A migrant is a person who has changed his/her usual place of residence from one migration-defining area to another at least once during the migration interval.

**Migration rate/In-migration rate/Outmigration rate:** for population projection purposes, is the proportion of survivors at the end of a projection interval (of the initial population or of births during the interval) who live in a different place of residence at the end of the interval than they lived at the beginning of the interval or at birth. The proportion is an outmigration rate if the base of the proportion is the number of persons in the origin population, and an in-migration rate if the base of the proportion is the number of persons in the destination population. The rate is age-sex-specific if the survivors are restricted to persons in a particular age/sex group, “age” here being understood to include persons born during the interval.

**Net Migration:** It is the difference between the number of in-migrants and the number of out-migrants.

**Population Projection:** It is an estimate of future population by considering changes in a population due to fertility (births), mortality (deaths) and migrations.

**Population Pyramid:** A diagram showing the comparison of a human population by sex and age at a given time, consisting of a pair of histograms, one for each sex, laid horizontally in ascending order of age groups with a common base. The diagram is intended to provide a quick overall comparison of the age and sex structure of the population.

**Population Growth:** is the increase or decrease in population numbers during a particular time interval. “Population change” is logically more appropriate, since numbers may decline as well as increase, but population change might mean any kind of change, whereas population growth will generally be understood to mean a change in the number of persons.

**Population Projection:** as a verb, this is the calculation of future population numbers based on specific quantitative assumptions about future births, deaths and migrations. As a noun, it is the results of such a calculation.

**Sub-national population:** may be defined as the population of a specific geographic area within the territory of a country or as the population of an administrative area below the national level, such as regions and tinkhundla.

**Sex Ratio:** The number of males to the number of females usually expressed as a percentage.

**Base Population:** It is the population that has been adjusted for errors on age due to misreporting to give a more fitting demographic pattern.

**Total Fertility Rate:** Total Fertility Rate (TFR) is the average number of children born alive to a woman during her life time if she were to bear children at each age in accordance with the prevailing Age-specific fertility rates. It is obtained by summing up all age-specific fertility rates for each year of the childbearing span.

**Total Fertility Rate (TFR):** is a summary measure of the level of fertility in a population. It is interpreted as the average number of children per woman that would be observed at the end of the reproductive age span for a birth cohort of women who experience given age-specific birth rates. When age-specific birth rates are given for five-year age groups, the TFR is calculated as five times the sum of the age specific birth rates for ages 15-19 through 45-49.

## ANNEXES: PROJECTION TABLES

**Table 5.1: Projected National Population by Single Years of Age by Sex Medium Variant**

| Age   | 2017    |         |           | 2018    |         |           | 2019    |         |           |
|-------|---------|---------|-----------|---------|---------|-----------|---------|---------|-----------|
|       | Male    | Female  | Total     | Male    | Female  | Total     | Male    | Female  | Total     |
| Total | 538 957 | 567 494 | 1 106 451 | 545 452 | 574 640 | 1 120 092 | 551 905 | 581 617 | 1 133 522 |
